

A non-detection is an upper bound, not a zero

The same measurement, the same legal threshold, read two ways

What the record stores

a number, indistinguishable from a measured zero

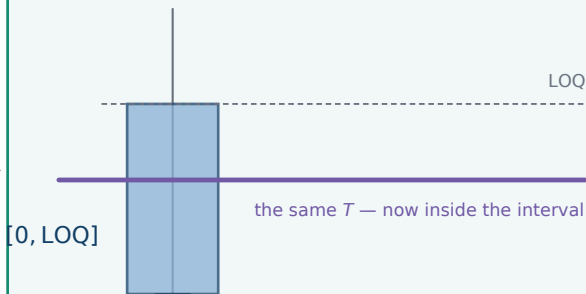

Compliant

one of two possible verdicts

What the measurement established

an interval: the analyte may be present below the limit

Cannot be determined

a verdict the two-valued model cannot express

CENSO binds the quantification limit to the analytical run rather than to the instrument, so the interval survives into the data.

45%

of 33 million European samples
lie below the quantification limit

32%

of assessments in 2020–2024 cannot be
determined from the record as reported
(44% over the whole record)

40%

of assessments against a European
standard use a method failing the
legal LOQ criterion (2009/90/EC)

EEA Waterbase: 4.2 million river station-years, 637 substances, 37 countries.

The reporting defect was repaired: no station-year has declared neither flag nor limit since 2013, and that repair is the whole of the fall above.

The analytical one was not — the method fails the standard in 19 % of recent assessments against 17 % over the whole record.
